

Analysis of Algorithms | Set 4 (Analysis of Loops)

Difficulty Level : Easy • Last Updated : 12 Nov, 2021

We have discussed [Asymptotic Analysis](#), [Worst, Average and Best Cases](#) and [Asymptotic Notations](#) in previous posts. In this post, an analysis of iterative programs with simple examples is discussed.

1) $O(1)$: Time complexity of a function (or set of statements) is considered as $O(1)$ if it doesn't contain loop, recursion, and call to any other non-constant time function.

```
// set of non-recursive and non-loop statements
```

For example, [swap\(\) function](#) has $O(1)$ time complexity.

A loop or recursion that runs a constant number of times is also considered as $O(1)$. For example, the following loop is $O(1)$.

```
// Here c is a constant  
for (int i = 1; i <= c; i++) {
```

incremented/decremented by a constant amount. For example following functions have $O(n)$ time complexity.

```
// Here c is a positive integer constant
for (int i = 1; i <= n; i += c) {
    // some O(1) expressions
}

for (int i = n; i > 0; i -= c) {
    // some O(1) expressions
}
```

3) $O(n^c)$: Time complexity of nested loops is equal to the number of times the innermost statement is executed. For example, the following sample loops have $O(n^2)$ time complexity

```
for (int i = 1; i <= n; i += c) {
    for (int j = 1; j <= n; j += c) {
        // some O(1) expressions
    }
}
```

For example, [Selection sort](#) and [Insertion Sort](#) have $O(n^2)$ time complexity.

4) $O(\text{Log}n)$ Time Complexity of a loop is considered as $O(\text{Log}n)$ if the loop variables are divided/multiplied by a constant amount.

```
for (int i = 1; i <=n; i *= c) {  
    // some  $O(1)$  expressions  
}  
for (int i = n; i > 0; i /= c) {  
    // some  $O(1)$  expressions  
}
```

For example, [Binary Search\(refer iterative implementation\)](#) has $O(\text{Log}n)$ time complexity. Let us see mathematically how it is $O(\text{Log}n)$. The series that we get in the first loop is $1, c, c^2, c^3, \dots c^k$. If we put k equals to $\text{Log}_c n$, we get $c^{\text{Log}_c n}$ which is n .

5) $O(\text{LogLog}n)$ Time Complexity of a loop is considered as $O(\text{LogLog}n)$ if the loop variables are reduced/increased exponentially by a constant amount.

```
//Here fun is sqrt or cuberoot or any other constant root
for (int i = n; i > 1; i = fun(i)) {
    // some O(1) expressions
}
```

See [this](#) for mathematical details.

How to combine the time complexities of consecutive loops?

When there are consecutive loops, we calculate time complexity as a sum of time complexities of individual loops.

```
for (int i = 1; i <=m; i += c) {
    // some O(1) expressions
}
for (int i = 1; i <=n; i += c) {
    // some O(1) expressions
}
```

Time complexity of above code is $O(m) + O(n)$ which is $O(m+n)$

If $m == n$, the time complexity becomes $O(2n)$ which is $O(n)$.

How to calculate time complexity when there are many if, else statements inside loops?

As discussed [here](#), worst-case time complexity is the most useful among best, average and worst.

When the code is too complex to consider all if-else cases, we can get an upper bound by ignoring if-else and other complex control statements.

How to calculate the time complexity of recursive functions?

The time complexity of a recursive function can be written as a mathematical recurrence relation. To calculate time complexity, we must know how to solve recurrences. We will soon be discussing recurrence solving techniques as a separate post.
